

DEVICE AND METHOD FOR IDENTIFYING CABLES**Field of the Invention**

5 The present invention relates to a device for identification marking of cables. In particular, the invention concerns cables that are provided with unambiguous markings at least in their end sections. The invention also relates to a method for identification marking of cables.

Background of the Invention

10 In the last few years, the amount of cable in use has increased significantly. Especially in the area of computers and telecommunication devices, there has been a large increase due to the development of new devices and technologies such as new telephone systems, local area networks, and so forth.

15 These systems often need miles of electric cable in order to interconnect devices located far apart. Such cables are needed to connect, for example, a master control unit, such as a switch or a telephone system, with outlets or the like spread over one or more buildings of a large campus.

20 Frequently, racks carrying hundreds of connectors are arranged in a single room. In order to be able to find a particular connector within this jumble, the cable ends are normally marked. If this is not the case, a cable must be trailed from one end to the other, which is generally very cumbersome.

For marking cables, the following methods are used today:

- Installation of marking rings carrying letters or numbers
- Installation of a labeled heat-shrinkable sleeve
- Fastening of plastic slips.

5 U. S. Patent 4,579,759 discloses the use of an inscribable cable
marking strip comprising a strip of an adhesive tape having a self-
adhering bottom side and carrying an inscribable marking section. The
beginning of the inscribable marking section is located at a distance
10 from the adjacent front end of the adhesive tape to define an
unlettered, transparent starting section of the strip which may be
pressed onto the cable without soiling the marking section or
smudging the lettering applied to it.

Several other cable marking systems are known, for instance using
codes preprinted on the sleeve or printed on labels glued onto the
sleeve, and the like. A cable marking system is also known wherein
ring-shaped marking elements are introduced in a recess on the
outside of the support.

However, such systems have the disadvantage that they are either very
costly or time consuming, or that tapes, rings, and the like may slip
20 or fall off, so that the marking is no longer discernible.

Therefore, it has been proposed to mark the cable itself. For
example, U. S. Patent 4,370,542 describes a method for marking an
identification at pre-selected intervals along a length of cable by
a laser marking device. However, it is still difficult to find such
25 a marked cable when mounted to a connector and arranged among a
multitude of other cables.

It is therefore an object of the present invention to provide a
device for identification marking of cables that is easy to handle

and allows easy location of a particular cable among others.

It is still another object of the present invention to provide a method for identification marking of such cables that allows marking without the use of additional equipment.

5 **Summary**

According to the present invention, an improved strain relief clamp for a connector mounted on a cable includes a transparent portion such as a rectangular window or a transparent ring held in a groove. The cable, which is provided with unambiguous identification markings at its end region, is cut to length so that an identification marking of interest appears directly behind the connector's shell when the connector is mounted on the cable. When the strain relief clamp is installed on the connector, the identification marking of interest is visible through the transparent portion of the strain relief clamp.

10 **Brief Description of the Drawings**

The invention will hereinafter be described in more detail in connection with the accompanying drawings, in which

Fig. 1 schematically shows a cable that is provided with unambiguous markings at least in its end section;

20 Fig. 2 schematically depicts the cable of Fig. 1 that is connected to a connector;

Fig. 3A to 3C schematically show the cable of Fig. 2 in connection with a respective strain relief clamp; and

25 Fig. 4A to 4C schematically depict several embodiments of the device according to the invention.

Detailed Description

5 The present invention is not restricted to electric cables, but can be used with every kind of cable provided with a strain relief clamp, regardless of whether it carries electricity, fluids, gases, air, or other media. Thus, the invention may be applied to every form of cable, including round, tubular, flat, or rectangular cables. However, the invention is described below with respect to an electric cable only for clarity.

10 As shown in Fig. 1, a cable 10 is marked with unambiguous identification markings 12 at least in its end sections 14. This can be done by applying numbers or letters or combinations thereof by means of color printing or laser marking. The number of positions is restricted due to limitations of the area of the cable. Consequently, it is sensible to use numbers or letters having two digits. These markings may be repeated on the whole cable within regular or irregular intervals. It is, however, necessary that these markings be unambiguous, i.e., they must unequivocally identify a particular cable or part thereof.

20 The cable 10 thus marked is cut such that the marking of interest 16, i.e., the marking that is to define the respective cable or part thereof, is visible directly behind the shell of a connector 18 when the connector 18 is mounted to the cable 10. This is shown in Fig. 2.

25 The connector 18 may be an RG45 or Western connector or an RJ connector. However, other connectors are suitable as well, and the invention is not restricted to these connectors. The connector 18 shown in Fig. 2 may be provided with a safety hook 20 which serves to lock the connector in place. Fig. 3A shows the arrangement of Fig. 2 where a metal grounding 22 has been added to the connector 18.

5 A strain relief clamp 24, which may be put on the cable 10 before mounting the connector 18, is now installed on the connector 18 as shown in Fig. 3C. The strain relief clamp 24 may at the same time function as an antikink protective sleeve by means of an antikink component 26.

10 According to the invention, the strain relief clamp 24 is provided with a transparent portion for making visible the marking of interest 16 present on the cable 10 after the strain relief clamp 24 has been installed on the connector 18. The transparent portion may be a rectangular window 28, through which the marking of interest is readable, as shown in Fig. 4A. In case the marking of interest includes a long row of digits or letters (represented by the word "LANSERVER" in Fig. 4B), the strain relief clamp 24 and thus the window 28 may be elongated so that even long words may be read.

20 Fig. 4C represents another embodiment of the invention. Here, the transparent portion is a transparent ring 30 that is arranged around the strain relief clamp 24. The ring 30 preferably extends 360 degrees around the clamp 24 and may be either tightly connected to the clamp 24 or movably guided within a groove 32 present in the clamp. In another advantageous embodiment, only the part of the ring 30 above the marking is transparent, whereas the rest is made of a substantially opaque material.

Of course it is possible and advantageous to provide the cable 10 with the inventive strain relief clamp 24 at both ends thereof.

25 Another advantageous embodiment of the present invention provides for an additional colored marking at one or both ends of the cable 10.

With the device according to the invention it is possible to easily and quickly detect an identification marking on the respective end portions of a particular cable, even if the cable is bunched together

with other cables. Thus, fault analysis is simplified and cable problems can now more easily be solved.

Still another advantage of the present invention concerns marked, prefabricated cables of the type known as patch cables. The manufacturer of such patch cables may use a lasermarker to produce as many patch cables as needed. The cable can be produced according to known procedures and can then be marked without additional effort.
